

# Homework 2: Answers

Profs. John McLeod & Arash Reyhani

ECE3375, Winter 2022

1. *Problem*: Which microprocessor is used in the labs for this course?
  - (a) ARM®Cortex-A9
  - (b) ARM®Cortex-M3
  - (c) Intel Core-i7
  - (d) Microsoft Word

Please note that the order of these options is randomized.

*Solution*: The ARM®Cortex-A9 is used in the labs in this course. This information is found in the course notes and in various lab manuals and documentation.

The ARM®Cortex-M3 (or ARM®Cortex-M4) is used in the textbook, but is not used in the labs for this course.

2. *Problem*: A line of code in ARM Assembly used in the labs in this course that contains an instruction must have the following format:

```
1 label: mnemonic operand1, operand2, operand3 /* comment */
```

Please choose the best description of this format from the options given below.

- (a) A mnemonic is always necessary.  
The number of operands depends on the mnemonic; some require zero.  
Comments are always optional.  
A label is optional but often needed for branch or if-then statements. Each label must be unique within the entire program code.
- (b) At least one operand is necessary.  
The mnemonic is optional.  
A label is only required for new distinct sections of code.  
Comments are always optional.
- (c) A mnemonic and all three operands are necessary.  
Comments are always optional.  
A label is only required after a directive.
- (d) Every instruction must have a label, a mnemonic, and a comment.  
The number of operands required depends on the mnemonic.

Please note that the order of these options is randomized.

*Solution:* A mnemonic is always necessary: a *line of code* does not require a mnemonic — it may be a label or a comment — but an *instruction* always requires a mnemonic. The number of operands depends on the mnemonic; some require zero.

- The nop mnemonic is an example of a mnemonic that requires no operands. It does nothing (it is used to idle or to pad code so other instructions align at particular memory addresses).
- This wasn't discussed in class, but you can deduce this was the correct answer by eliminating the other incorrect options.

Comments are always optional. A label is optional but often needed for branch or if-then statements. Each label must be unique within the entire program code.

3. *Problem:* Some registers and memory cells in a microcontroller are initialized as shown. The following code is executed:

```
1 mov r2, #4
2 ldr r3, [r0]
3 sub r0, r0, r1
4 add r1, r3
5 ldr r3, [r0]
6 add r2, r3
7 str r2, [r0]
```

What are the contents of the registers and memory after this code is executed?

*Solution:* Trace the code line-by-line.

- Register **r2** now holds the value 4.
- Register **r3** holds the contents of memory address **r0** = **0x2000**, so **r3** contains **0x0040**.
- The value in register **r1** is subtracted from the value in register **r0** and stored in **r0**.  $0x2000 - 0x0004 = 0x1FFC$ .
- The values in registers **r1** and **r3** are added and stored in **r1**.  $0x0004 + 0x0040 = 0x0044$ .
- Register **r3** holds the contents of memory address **r0** = **0x1FFC**, so **r3** contains **0x1111**.
- The values in registers **r2** and **r3** are added and stored in **r2**.  $0x0004 + 0x1111 = 0x1115$ .

r0	0x0000 2000
r1	0x0000 0004
r2	0x0000 0000
r3	0x0000 0000

0x0000 2008	0x0000 369C
0x0000 2004	0x0000 2468
0x0000 2000	0x0000 0040
0x0000 1FFC	0x0000 1111

- The value stored in `r2` is written to the memory address in `r0`. The memory starting at address `0x1FFC` now holds the value `0x1115`.

<code>r0</code>	0x0000 1FFC
<code>r1</code>	0x0000 0044
<code>r1</code>	0x0000 1115
<code>r1</code>	0x0000 1111

0x0000 10FC	0x0000 369C
0x0000 10F8	0x0000 2468
0x0000 10F4	0x0000 0040
0x0000 10F0	0x0000 1115
